

Evidence combination: tier ratios (Q1) and boundary paths (Q2)

Piecewise: exact LP/P posteriors via point-sum, small LR-product mismatch · Tavgitian: exact LR ratios, drifting LP/P posteriors

Q1: LR+ value per point, by tier
 Tavgitian: one flat value for all tiers (exact 1:2:4:8)
 Piecewise: splits — VS (upper segment) $\neq$ Su/M/S (middle segment)

Q1: Does tier doubling hold? $LR+(2k) / LR+(k)^2$
 $= 1$ means $2 \times \text{Supporting} = \text{Moderate}$, $2 \times \text{Strong} = \text{VS}$, etc.
 S+S $\rightarrow$ VS crosses the T=6 knot — largest deviation

Q2: LP boundary (T=6) combination paths
 Piecewise: point-sum = 0.90 exactly · LR-product may differ
 Grey = Tavgitian boundary drift (its failure mode)

Q2: P boundary (T=10), lower-segment paths only (no VS)
 All codes ≤ 4 , total crosses T=6 knot on way to T=10
 Grey = Tavgitian boundary drift at T=10

Q2: P boundary (T=10), paths involving VS (code 8)
 VS in upper segment, companion codes in middle segment
 Grey = Tavgitian boundary drift at T=10

Summary: Tavgitian boundary drift vs piecewise combo error
 at $p=0.10$ and $p=0.25$ · Piecewise combo error measured as max across paths
